1 Purpose of this document

This document was created as part of the project CoEXist\(^1\). The intent of this document is to provide a comprehensive description on modelling of automated vehicles with PTV Vissim 11 or later versions. Adjustments to different types of models, in simulation software other than PTV Vissim, can be inferred from the recommendations given here, but caution must be taken especially when the driving behaviour parameters are based on a different type of model (e.g. models apart from Wiedemann).

1.1 What is possible in PTV Vissim?

Automated vehicles can have different automation levels\(^2\), different automation functions, different sensor equipment, and different driving logics. The modelling technique depends on the scope of information you have about the automated vehicles.

With driving logics algorithms

If the driving logics algorithms are known or under development, one of PTV Vissim’s interfaces can be used to couple the algorithms with PTV Vissim. This allows direct testing of algorithms, giving the ability to visualize and compare the interaction between automated vehicles equipped with the algorithms and conventional vehicles provided by the PTV Vissim model. This process is described in ‘D2.2 Technical Report on connecting AV control logic and AC Simulator’ available on the CoEXist website.

Without driving logics algorithms

If the algorithms are not known, the driving behaviours offered by PTV Vissim can be used as a starting point for the model. The expected driving behaviour of automated vehicles should be always considered. Saying e.g. automation level 4 is insufficient for microscopic simulation because it requires knowledge or assumptions about the behaviour when following lane changing, reacting on signals or resolving conflicts, e.g. gaps, thresholds, etc. Using the human driver as a benchmark, expected behaviour of automated vehicles in terms of desired speed or acceleration can be defined (following headway, its variability, etc.). Some suggestions are provided by in 2 AV characteristics & assumptions for more information.

1.2 Communication and cooperation

Basic cooperation features are implemented in PTV Vissim already. However, these have been introduced to replicate how humans cooperate. Cooperation beyond that scope needs to be reflected another way.

\(^1\) See [https://www.h2020-coexist.eu/](https://www.h2020-coexist.eu/)

\(^2\) See SAE Taxonomy and Definitions for Terms Related to Driving Automation Systems for On-Road Motor Vehicles (J3016) [https://www.sae.org/standards/](https://www.sae.org/standards/)
Communication and cooperation might be a complex process with complex or simple outputs and impacts. For example, if the impact of communication between vehicles leads to small headways between them, you might achieve this by changing the driving behaviour parameters, especially CC0, CC1, CC2, CC6. See general PTV Vissim help for parameter description - Defining the Wiedemann 99 model parameters.

If the communication leads to complex longitudinal and lateral maneuvers, then you would likely need to use one of the PTV Vissim interfaces and describe the maneuvers as an algorithm. Communication in vehicle platoons including joining or leaving the platoon will be provided as feature in future service pack of PTV Vissim. See section 3.2.8 Platooning for more information.

1.3 The CoEXist project

Many AV-related enhancements and new features in PTV Vissim have been implemented within the project CoEXist. CoEXist is a European project (May 2017 – April 2020) which aims at preparing the transition phase during which automated and conventional vehicles will coexist on cities’ roads. For more information see https://www.h2020-coexist.eu/.

2 AV characteristics & assumptions
2.1 Field data

Field data from the test track in Helmond (NL) collected as part of CoEXist\(^3\) has shown for tested automated vehicles:

- Almost a linear relationship between headway and speed when following a manually driven car or an automated car without car-to-car (C2C) communication.
- A linear deterministic relationship between headway and speed when following another automated vehicle with car-to-car (C2C) communication.
- Oscillations during vehicle following are small with little variation in comparison with human drivers.
- No stochastic variation in driveaway behaviour. That was observed when vehicle accelerated on green signal at the intersection.

To reproduce the behaviour observed on the test track, it is necessary to change the driving behaviour parameters based on Wiedemann 99 model and use additional features developed for this purpose. See section 3.2 AV related features for more information.

2.2 AV Driving logic

Each automated vehicle uses a driving logic. Instead of distinguishing between car manufacturer’s or company’s driving logics, CoEXist works with 4 fundamental driving logics described by their major principles and capabilities. The logics are named rail safe, cautious, normal, and all-knowing.

The driving logics cautious, normal and all-knowing are part of the PTV Vissim default.inpx file as separate driving behaviours. They are based on the Wiedemann 99 car-following model with adjusted driving behaviour parameters and additional features developed for PTV Vissim 11. See section 3.2 AV related features for more information.

The rail safe driving logic is not included in PTV VISSIM DEFAULT.INPX file because of its special nature and application area.

Rail safe

This driving logic requires the appropriate parameters in addition to a special modelling approach to be in line with the driving logic principles. The rail safe driving logic describes a deterministic behaviour that represents the closed, controlled environment found at ports or within factories. It is characterized by the presence of physically separate lanes or large lateral distances, a pre-defined path that the vehicles follow, no lane change, and no unsignalized intersection. Furthermore, the brick wall stop distance always remains activated, see the feature enforce absolute braking distance, section 3.2.1. Enforce absolute braking distance. The modeller needs to keep all these specific details in mind.

Cautious

\(^3\) See “D2.6 Technical report on data collection and validation process” for additional information about the data collection process. Report available on www.h2020-coexist.eu.
The vehicle observes the road code and always adopts a safe behaviour. The brick wall stop distance is always active, see the feature **enforce absolute braking distance** and unsignalized intersections and lane changes are possible, but the vehicle will maintain large gaps. See section 3.2.1 Enforce absolute braking distance for more information.

**Normal**

The vehicle behaves like a human driver with the additional capacity of measuring distances and speeds of the surrounding vehicles with its range of sensors.

**All-knowing**

The vehicle has profound awareness and predictive capabilities, leading mainly to smaller gaps for all manoeuvres and situations. A kind of cooperative behaviour is expected.

### 2.3 Reduction of stochastics

Stochastics have been implemented into PTV Vissim to reflect the randomness of human driving behaviour. Two types of stochastics are available in PTV Vissim:

**Explicit stochastics**

Is defined by functions and distributions which the user can change directly.

**Implicit stochastics**

Is hard-coded and cannot be changed by the user. However, starting with PTV Vissim 11, this can be switched off (is on by default) in the dialog or list of driving behaviours (tab Following). See section 3.2.2 Use implicit stochastics for more information.

#### 2.3.1 Functions

Functions are accessible through the main menu: **Base Data > Functions**.

It is expected that automated vehicles will behave deterministically instead of stochastically like human drivers. This might have implications on the acceleration and deceleration behaviours. Based on this assumption, the modeler can reduce the spread of values for individual vehicles for:

- Desired acceleration
- Desired deceleration
- Maximum acceleration
- Maximum deceleration

The reduction can be done by simply changing the max and min curves, bringing them closer to the median curve or putting them on the median curve:
2.3.2 Distributions

Distributions are accessible through the main menu: Base Data > Distributions.

2.3.2.1 Desired speed

The distribution function of desired speeds is a particularly important parameter since it has an impact on link capacity and achievable travel times. The desired speed is the speed the driver wants to drive. The real speed is a result from interaction with other drivers and objects in the simulation, and each vehicle is assigned an individual desired speed from a distribution. With human drivers, a large spread of desired speeds can be observed. However, automated vehicles may operate with a much lower spread because they likely obey speed limits. Therefore, the automated vehicles might get different desired speed distributions than the conventional vehicles.

To do so, create a new speed distribution used by automated vehicles only and set appropriate boundaries.
2.3.2.2 Time

Time is an important distribution because it is used to define the CC1 driving parameter. The time has impact on the capacity, see PTV Vissim Help Defining the Wiedemann 99 model parameters for details. CC1 is a time distribution of the speed-dependent part of desired safety distance. Each time distribution may be empirical or normal. Each vehicle has an individual, random safety variable. PTV Vissim uses this random variable as a fractile for the selected time distribution CC1. The randomness can be switched off by deactivating use implicit stochastic. See section 3.2.2 Use implicit stochastics for more information.

The appropriate value(s) for the time distribution for CC1 parameter depends on the expected behaviour of the automated vehicle. The value might be larger value for cautious vehicles or smaller value for all-knowing vehicles in comparison with the value used for conventional vehicles by default (0.9 s).

3 Simulation with PTV Vissim internally

3.1 Driving behaviour settings on a link level

PTV Vissim allows to define vehicle class-specific driving behaviours for each link or connector in the network. This means different vehicles can behave differently on the same link/connector, e.g. cars and HGVs or conventional cars and automated cars.

3.1.1 Driving behaviour

PTV Vissim offers predefined driving behaviours, which can be easily adjusted by the user. We recommend duplicating a specific driving behaviour(s), adjusting them if necessary, and then using it in your simulation.
Note: The driving behaviours for automated vehicles are not extensively tested and compared with the real world yet because of a simple fact. There are only few automated vehicles on the roads as of 2018 and they are capable of only the simpler part of the driving tasks (following). Driving parameter values proposed by PTV are based on empirical studies and co-simulation data collected within CoEXist (following behaviour only) as well as on several assumptions. If your assumptions differ, consider changing the parameter values and features settings.

3.1.2 Link behaviour types

In the list of Link behavior types, you can specify which driving behaviour will be used by default and in the coupled right-hand-side-list Driving behaviours you can specify additionally driving behaviours for individual vehicle classes. This will allow e.g. a vehicle from vehicles class Car_AV_cautious behave differently compared to a conventional car.

![Figure 5 Example of how to set different driving behaviour to the vehicle classes](image)

3.1.3 Spatial extent

In the real world or in a scenario, the study area might be spatially divided into several zones where different driving logics are required. For example, there might be an AV-friendly part of the city, where the vehicles could use normal or all-knowing driving logic, but also another part of the city where a cautious driving logic is needed. To achieve this, you need to define link behaviour types to cover all possible behaviours of your automated vehicle and then assign this link behaviour type to links in the corresponding part of your model. As a result, the same vehicle can use different driving logics in different parts of the network.

![Figure 6 Example of how to set different driving behaviour for different link types](image)

Analogically, a highly developed automated vehicle can drive with all-knowing driving behaviour through the network but act as a rail safe or cautious vehicle in a parking garage or shared space.

Example from the CoEXist project:
The scenario includes 3 different AV vehicle classes, and each vehicle class uses a specific driving logic for a specific road type (see the Table 1 below). In this case, you can define four link behaviour types (motorway, arterial, urban street, shared space) combined with four driving behaviours (cautious, normal, all-knowing, manual – for each of them an urban and freeway option is defined because of differences in lane change parameters) for three AV vehicle classes (basic AV, intermediate AV, advanced AV).4

Table 1 Specification of which driving logic basic AVs, intermediate AVs and advanced AVs could use in different road environments.

Figure 7 Scenario including 3 different AV vehicle classes, and each vehicle class uses a specific driving logic for a specific road type

3.2 AV related features

Multiple additional attributes are available in the driving behaviour dialogs since PTV Vissim 11. Most are required mainly for modelling of CAV (connected and/or automated vehicles), but many can also be used for calibration of human behaviour. The added attributes are explained in the following chapters.

4 For more information, please refer to deliverable 1.4 “Scenario specification for eight use cases”
3.2.1 Enforce absolute braking distance

If the attribute **Enforce absolute braking distance** (a.k.a. brick wall stop distance) is checked, vehicles using this driving behaviour will always make sure that they could brake without a collision, even if the leading vehicle comes to an immediate stop (turns into a brick wall).

This condition applies also:

- to lane changes for the vehicle itself on the new lane and for the trailing vehicle on the new lane and
- to conflict areas for the following vehicle on the major road.
- Following:
3.2.2 Use implicit stochastics

If the attribute Use implicit stochastics is unchecked (default is checked), a vehicle using this driving behaviour does not use any internal stochastic variation that is meant to model the imperfection of human drivers. For all distributions that cannot be explicitly set by the user, a median value is used instead of a random value.

This affects:

- the safety distances
- the desired acceleration
- the desired deceleration
- the estimation uncertainty for braking decisions

The three former variables are partially defined by attributes/functions accessible to the user, so this

---

5 Rear gap = time to brake to full stop 1 m in front of the conflict area
part is still valid, but the additional stochastic spread included in the internal model is reduced to zero.

Deactivating **Use implicit stochastics** is recommended for all automated vehicles or for that part of the infrastructure, where the vehicle drives in automated mode.

### 3.2.3 Number of interaction objects and vehicles

The attribute **observed vehicles** from PTV Vissim 10 has been split into two attributes:

- **Number of interaction objects** refers to vehicles and internal objects (reduced speed areas, stop signs, priority rules, red signal head)

- **Number of interaction vehicles** refers only to real vehicles

The number of interaction vehicles defines an upper limit for the observed leading vehicles, therefore, for example, this could be set to 1 for automated vehicles with a sensor equipment that cannot see through the leading vehicle. A red signal downstream of the leading vehicle would still be observed, but not the second real vehicle downstream.

**Examples**

- **Number of interaction objects**: 3 (first three objects are *visible* for the red car)
- **Number of interaction vehicles**: 1 (only one vehicle is *visible* for the red car)

![Figure 12 Example of the use of the new attributes: number of interaction objects and number of interaction vehicles](image)

Another situational examples:
Figure 13 Additional examples of the use of the new attributes: number of interaction objects and number of interaction vehicles.

Per default, within the Wiedemann 99 model, the number of interaction objects is set to 2 and the number of interaction vehicles is set to 99, which is the maximum possible value.

It is possible to enter a higher number of interaction vehicles than objects; however, the number of interaction objects is always the limiting factor.

If the number of interaction vehicles is equal or higher than the number of interaction objects, you get the same setup as in PTV Vissim 10 or earlier releases.

If you set the number of interaction vehicles lower than the number of interaction objects, you will limit the number of visible vehicles within the visible objects.

### 3.2.4 Headway based on leader vehicle class

On the new tab page **Car following model** in the driving behavior dialog or in the coupled list **Vehicle Class Following Behavior**, some of the parameter values affecting the desired safety distance can be specified per vehicle class of the leading vehicle now, in addition to the value for all other vehicles.

This can be used, for example, for having connected vehicles using a smaller safety distance when following another connected vehicle but a larger safety distance when following a human driver or a bike.
3.2.5 Increased acceleration

This attribute is accessible through the Driving behaviors list and can be set in dependency on leading vehicle class in the coupled list Vehicle class following.

The normal human acceleration behaviour cannot use reliable information about the future behaviour of the leading vehicle, and therefore, normal Vissim vehicles tend to fall behind when the leading vehicle is accelerating. But automated vehicles, especially if using car-to-car (C2C) communication, can use a tight coupling with small headways.

If the attribute Increased acceleration is set to a higher value than 100%, a vehicle using this driving behaviour can accelerate with the given percentage of its normal desired acceleration, but not exceeding its maximum acceleration if the leading vehicle is faster and accelerating.
3.2.6 Occupancy distribution with zero passengers

For empty automated vehicles (without passengers), it is now possible to define an empirical occupancy distribution which contains zero passengers. You can do so in the coupled list Data points.

![Figure 17 The occupancy distributions / Data points list](image)

![Figure 18 Occupancy distribution is set to zero](image)
3.2.7 Consider vehicles in dynamic potential

The interaction between vehicles and pedestrians is mainly modelled as conflict areas, which do block a certain area if a vehicle or pedestrian is within the area or approached it. In this case, others are not allowed to use this area.

Vehicles blocking a conflict area can now be considered in the dynamic potential for conflicting pedestrians. If this option has been activated on a pedestrian link, pedestrians will not stop at a blocked conflict area, but will try to walk around it through the gaps between queued vehicles. For this, the lanes of a pedestrian link need to be sufficiently narrow. For example, lane widths of 0.6 m only, so that at least one lane conflict remains open between queued cars. Dynamic potential for pedestrian routes needs to be active.

![Image of pedestrians and vehicles interaction](image_url)

**Figure 19** Left-hand side: interaction pedestrians-vehicles when dynamic potential is disactivated, the pedestrians are waiting in front of the standing vehicles; right-hand side: interaction pedestrians-vehicles when dynamic potential is activated, the pedestrians are actively looking for and using the gaps between the standing vehicles

![Image of link dialog and network objects](image_url)

**Figure 20** Left-hand side: link dialog: activation of “consider vehicles in dynamic potential”; right-hand side network objects needed

The parameter **G for vehicles in dynamic potential** affects the general strength of vehicles (default value: 3). This attribute also influences the oncoming lane.

3.2.8 Platooning

Platooning as a parametrized feature in PTV VISISM GUI is planned to be implemented in the last quarter of 2018 and should available for PTV VisSim users with a service pack in 2019. A script-
3.3 Driving parameters

The tables in the following subchapters recommend the direction of change for the driving behaviour parameters to model CAVs. Specific numeric values proposed within CoEXist, which can be used as a starting setting, are available as three additional driving behaviours directly in the default network file, so they appear in the driving behaviour list after opening PTV Vissim or creating a new file, if you did not save your own default network file before without these new driving behaviours.

**Note:** The specific parameter values available within cautious, normal and all-knowing driving behaviour are not the only possible values. The development on the field of automated vehicles is fast and the resulting driving behaviour is influenced by many factors like legislation, legal aspects, hardware and software equipment, weather and visibility conditions.

3.3.1 Following behaviour

Because of deterministic behaviour of automated vehicles and to reflect much smaller oscillation in vehicle following:

- CC2 can be reduced up to zero
- CC4 and CC5 can be significantly reduced
- CC6 can be reduced up to zero

</tbody>
</table>

*if EABD is on, brick wall stop distance is guaranteed ** see PTV Vissim manual for detailed description
3.3.2 Lane change behaviour

For the lane change behaviour, the most important parameter is the Safety distance reduction factor, which is set to 0.6 by default in PTV Vissim. That means vehicles accept smaller gaps for lane change as for following.

Note: For automated vehicles, this parameter might be higher or lower in value in comparison to the default value based on the driving logic or assumed behaviour in lane change manoeuvres. There are different default values for urban and freeway driving behaviours. To include automated vehicles in a model, we recommend using two driving behaviours: one for urban roadways and another for freeway type of infrastructure.

<table>

<td>def</td>
</tr>
</tbody>
</table>

Note: Although the table above also contains the parameters for the Wiedemann 74 model, it is recommended to use Wiedemann 99 to simulate automated vehicles because of more options to control the behaviour through the driving parameters.

3.3.3 Lateral behaviour

There are no suggestions regarding lateral behaviour from CoEXist. Automated vehicles will likely try to keep the lateral position in the middle of the lane. There might be requirements for lateral distance to other road space users, especially to vulnerable road users. These can be defined class dependent on the tab Lateral in the driving behaviour dialog according to expected behaviour of the automated vehicle.
3.3.4 Signal control behaviour

For the signal control behaviour, defining the reduced safety distance factor in an appropriate way is important. This parameter is set to 0.6 by default. For automated vehicles, this can be set to 1 if it is expected that they do not change the safety distances in the proximity of a signalized intersection.

On the other hand, if it is expected that automated vehicles will also reduce the safety distances in proximity to signalized intersections, then set this value lower than 1. The proximity itself is described by reduced safety start (end) up (down) stream of stop line.

*only protected phase possible in AV-certified environment
** probably protected phases only, EABD must be on
*** requires that the AV can remember that it has made a decision for that particular signal head already, else: continuous check

3.4 AV – Penetration rates

While testing the future scenarios with automated vehicles, different penetration rates of different kinds of automated vehicles or driving logics are often of interest. To address this, it is possible to simply change the vehicle composition with the corresponding share of automated vehicle types. For example, to model 50% conventional, 30% cautious, and 20% normal, the settings should be:

Figure 21 Example of the settings for a model with the following share of driving behaviour: 50% conventional, 30% cautious, and 20% normal

3.5 Future adaptation of human drivers

With a growing share of automated vehicles in the traffic flow, the behaviour of other human drivers might also change. Because of lack of empirical data and real experience with higher penetration rates of automated vehicles as of 2018, specific recommendation cannot be provided, except that this aspect should not be overseen and should be taken into account when listing the assumptions of the model.

3.6 Safety aspects

For conventional vehicles with human drivers, the safety aspects can be investigated using the
SSAM model (Surrogate Safety Assessment Model⁶). According to the SSAM software user manual, “it provides guidance on the installation and use of the software, which is used to perform surrogate safety analysis of a traffic facility, such as a signalized intersection. It does so by processing vehicle trajectory data from a given microscopic traffic simulation to identify the frequency of conflicts—where two vehicles are on a collision course and one vehicle must make an evasive maneuver to avoid a collision. Such surrogate measures have been shown to correlate to some degree with the historical frequency of crashes at intersections.”

Unfortunately, due to the lack of data on the frequency of crashes at intersections with automated vehicles, there is no experience in applying such techniques for automated vehicles and the results should be handle with precaution. It is not clear whether the thresholds used in SSAM for defining conflicts and severity of conflicts are also valid for automated vehicles, especially for the all-knowing driving logic, which might be able to drive with short safety distances without being unsafe or at least not as unsafe as a human driver would be in the same situation.

3.7 Examples

All AV-related examples are available in …\EXAMPLES TRAINING\AUTOMATED VEHICLES (AV) folder. Each example is described in detail in a PDF document explaining the goal and modelling technique.

Base network AV

This file can be used as a template to start a new model or read additional network object types for basic automated vehicle settings and three CoEXist automated vehicles driving logics.

Lateral Space

Demonstration of possible consequences of automated vehicles on road capacity at signals and weaving sections. A simplistic approach where a typical driving behaviour of automated vehicles (AV) can be described based on some basic AV characteristics.

Simple Intersection

Demonstration of possible consequences of automated vehicles in simple intersection in terms of delay and queue length. Automated vehicles are modelled in a simple way as a vehicle class with modified driving behaviour parameters. Driving behaviour parameters were modified with couple of simple assumptions about the behaviour of automated vehicles.

4 Simulation with PTV Vissim externally

Simulation with PTV Vissim externally means using PTV interfaces. This approach is needed when one wants to use its own or third-party algorithms and/or tools, e.g.:

---

⁶ See https://www.fhwa.dot.gov/publications/research/safety/08049/ for additional information
• couple PTV Vissim to a driver/cyclist/pedestrian training simulator
• control vehicle(s) with own driving logics algorithms
• simulate vehicle dynamics
• simulate sensors

4.1 PTV Vissim interfaces

4.1.1 COM

The Component Object Model (COM) describes how binary components of different programs collaborate. COM gives access to data and functions contained in other programs. Since Vissim version 4.0, data contained in Vissim can be accessed via the COM interface using Vissim as an automation server. The Vissim COM interface is automatically included when the software is installed. Since Vissim version 4.30, COM scripts can be called directly from the Vissim main menu.

Note: The Vissim COM interface is not included in the Demo version.

COM does not depend on a certain programming language. COM objects can be used in a wide range of programming and scripting languages, including VBA, VBS, Python, C, C++, C#, Delphi, and MATLAB. In the following examples, VBA is used most often. Exceptions using the programming language Python are marked explicitly.

• **Advantage:** The COM script has access to all data inside Vissim which can be made visible in a list window (and some more).
• **Restriction:** The COM script cannot affect the lateral movement of the vehicle. No direct lane change can be performed (only a desired lane change). And COM may be slow.

Executing a script

There are two options to execute a script directly within Vissim, if it is written in VBS (Visual Basic Script), Java-Script or Python:

• Direct, single call of a script file: SCRIPTS - RUN SCRIPT FILE...
• Event-based scripts: SCRIPTS - EVENT-BASED SCRIPTS

Further information

For further information about COM, see these information sources:

• VISSIM 11 - COM INTRO.PDF in the Doc directory
• COM-Help in the PTV Vissim menu: Help > COM-Help
• COM BASIC COMMANDS ENG.PDF in …\EXAMPLES TRAINING\COM\BASIC COMMANDS
4.1.1.1 Examples

All COM examples can be found in: …\EXAMPLES TRAINING\AUTOMATED VEHICLES (AV)

Path Addition + Assignment.COM

A taxi vehicle serves random requests from an origin (pick-off) to a destination (drop-off). Once there is a new request (randomly created), the vehicle will first be sent to the pick-up point and then drive to the drop-off point.

Platooning.COM

Vehicles on a highway may form platoons, which means they travel at an identical speed and maintain a short and steady headway. This example includes the generation of platoons at the edge of the network as well as platoon operations such as vehicles closing the gap if a vehicle leaves the platoon and vehicles opening a gap to allow another vehicle to enter the platoon.

Speed At Signals - C2X.COM

Vehicles to infrastructure communication (C2X) for adjusting driving speed to arrive at signals at green. Connected automated vehicles (CAVs) receive the information about the upcoming signal and adjust their speed to arrive at green without stopping.

4.1.2 DriverModel

The External DriverModel DLL Interface of Vissim provides the option to replace the internal driving behaviour by a fully user-defined behaviour for some or all vehicles in a simulation run. The user-defined algorithm must be implemented in a DLL written in C/C++ which contains specific functions, as specified below.

During a simulation run, Vissim calls the DLL code for each affected vehicle in each simulation time step to determine the behaviour of the vehicle. Vissim passes the current state of the vehicle and its surroundings to the DLL and the DLL computes the acceleration/deceleration of the vehicle and the lateral behaviour, mainly for lane changes and passes the updated state of the vehicle back to Vissim.

The external driver model can be activated for each vehicle type separately in the dialog box Vehicle Type by checking the checkbox Use external driver model on the tab page External Driver Model and selecting a driver model DLL file and optionally a parameter file to be used. If this option is checked, the driving behaviour of all vehicles of this vehicle type will be calculated by the selected DLL. A subdirectory DRIVERMODELDATA\ must exist in the directory of VISSIM.EXE to avoid a warning message when Vissim is started.

- **Advantage:** Vissim passes only information of the nearby vehicles and about the upcoming road along the vehicle’s route to the DLL, so the DLL doesn’t need to know the network.
- **Restriction:** Information about priority rules and conflict areas is not passed to the DLL, so behaviour at intersections cannot be modelled. Routing cannot be changed but lateral behaviour and lane changes must be decided by the DLL.
4.1.2.1 Examples

There is not a full example available, but PTV provides supporting project files in ...

4.1.3 DrivingSimulator

The PTV Vissim add-on module Driving Simulator Interface allows to connect Vissim to a driving, cycling or walking simulator (DS). That DS can either be a simulator hardware used by a human or a piece of software representing the algorithms of a CAV or multiple CAVs.

Vissim provides the surrounding traffic (vehicles, bicycles, pedestrians) to be visualized in the DS, and the DS passes back the current position and orientation of the simulator vehicle(s) (bicycle(s) / pedestrian(s)). The vehicles and pedestrians in the Vissim network react to this simulator data as to
all other vehicles and pedestrians in the microscopic simulation model. In addition, Vissim passes traffic signal states to the DS for visualization, and the DS can set detectors in Vissim explicitly to affect the signalization.

The DS does not need to know the Vissim data model where the network is modelled from links, connectors, areas, ramps and obstacles. The DS needs to have its own world model (for simulation and visualization). As all vehicle and pedestrian positions are exchanged in cartesian world coordinates (x/y/z), the DS must be able to provide/use such coordinates, and the coordinates of the networks on both sides (Vissim / DS) must match precisely.

For additional details, see PTV VISSIM API - DRIVING SIMULATOR INTERFACE.PDF in ...

PTV VISION\PTV VISSIM 11\API\DRIVINGSIMULATOR_DLL\DOC

**DRIVINGSIMULATOR.DLL INTERFACE**

- **Driving Simulator DLL**
  - Calculate new position of driver vehicles for next simulation step

- **Vissim**
  - Simulation step of all vehicles in the network

Network needs to be known on both sides.

**4.1.3.1 Examples**

All examples can be found in: ...

PTV VISION\PTV VISSIM 11\API\DRIVINGSIMULATOR_DLL\EXAMPLE

**Driving simulator text client**

A simple example **DrivingSimulatorTextClient** is provided with the API package, including the example network file DRIVING_SIMULATOR_TEST.INPX and some additional files.

**Unity (game engine)**

This example demonstrates how PTV Vissim can be used to receive realistic traffic in Unity from PTV Vissim. When starting the Unity application, PTV Vissim opens, a network defined in PTV Vissim opens in Unity and vehicles controlled by PTV Vissim are displayed in Unity. In addition, one vehicle can be controlled by Unity like in a driving simulator.
4.2 Vehicles Dynamics & sensors (nano-simulation)

Simulation of detailed vehicle dynamics like power train, suspension, gear box, etc. or/and any kind of sensors is possible using a coupling (using DRIVINGSIMULATOR.DLL) with some external software providing such capabilities like PreScan, CarMaker, CarSim, dSPACE, or others.

5 Next steps

Within the CoEXist project, the new Vissim features will be demonstrated in five use cases in three CoEXist partner cities (Gothenburg, Milton Keynes and Helmond). For a detailed overview of the use cases, please check ‘D3.1 Completed experimental setup templates for eight use cases and AV-ready alternative design’ available on www.h2020-coexist.eu.
